Example: axi if <= init axi if signals(addr width, data width, id width, user width):

BFM Configuration record 't_axi_bfm_config'

Record element	Туре	C_AXI_BFM_CONFIG_DEFAULT	Description
max_wait_cycles	natural	1000	Used for setting the maximum cycles to wait before an alert is issued when waiting for ready and valid signals from the DUT.
max_wait_cycles_severity	t_alert_level	TB_FAILURE	The above timeout will have this severity
clock_period	time	-1 ns	Period of the clock signal.
clock_period_margin	time	0 ns	Input clock period margin to specified clock_period
clock_margin_severity	t_alert_level	TB_ERROR	The above margin will have the severity
setup_time	time	-1 ns	Setup time for generated signals. Suggested value is clock_period/4.
			An alert is reported if setup_time exceed clock_period/2.
hold_time	time	-1 ns	Hold time for generated signals. Suggested value is clock_period/4.
			An alert is reported if hold_time exceed clock_period/2.
bfm_sync	t_bfm_sync	SYNC_ON_CLOCK_ONLY	When set to SYNC_ON_CLOCK_ONLY the BFM will enter on the first falling edge, estimate the clock period, synchronise the output signals and exit ¼ clock period after a succeeding rising edge. When set to SYNC_WITH_SETUP_AND_HOLD the BFM will use the configured setup_time, hold_time and clock_period to synchronise output signals with clock edges.
match_strictness	t_match_strictness	MATCH_EXACT	Matching strictness for std_logic values in check procedures. MATCH_EXACT requires both values to be the same. Note that the expected value

can contain the don't care operator '-'.

MATCH_STD allows comparisons between 'H' and '1', 'L' and '0' and '-' in both values.

				· · · · · · · · · · · · · · · · · · ·
arregion_value	std_logic_vector(3 downto 0)	"0000"	(others=>'0')	Region indicator for a read transaction
aruser_value	std_logic_vector	x"01"	(others=>'0')	User-defined extension for the read address channel
rdata_value	t_slv_array	v_rdata_value	None	Output variable containing an array of read data
rresp_value	t_xresp_array	v_rresp_value	None	Output variable containing an array of read responses which indicates the status of a read transfer
ruser_value	t_slv_array	v_ruser_value	None	Output variable containing an array of user-defined extensions for the read data channel
rdata_exp	t_slv_array	t_slv_array'(x"ABCD", x"1234")	None	Array of expected read data values. A mismatch results in an alert 'alert_level'
rresp_exp	t_xresp_array	t_xresp_array'(OKAY, OKAY)	OKAY for all words	Array of expected read responses which indicates the status of a read transfer
ruser_exp	t_slv_array	t_slv_array'(x"01", x"01")	(others=>'0') for all words	Array of expected user-defined extensions for the read data channel
alert_level	t_alert_level	ERROR or TB_WARNING	ERROR	Set the severity for the alert that may be asserted by the procedure.
msg	string	"Set state active on peripheral 1"	None	A custom message to be appended in the log/alert.
scope	string	"AXI_BFM"	C_SCOPE ("AXI_BFM")	A string describing the scope from which the log/alert originates. In a simple single sequencer typically "AXI_BFM". In a verification component typically "AXI_VVC".
msg_id_panel	t_msg_id_panel	shared_msg_id_panel	shared_msg_id_panel	Optional msg_id_panel, controlling verbosity within a specified scope. Defaults to a common message ID panel defined in the UVVM-Util adaptations package.
config	t_axi_bfm_config	C_AXI_BFM_CONFIG_DEFAULT	C_AXI_BFM_CONFIG_DEFAULT	Configuration of BFM behaviour and restrictions. See section 2 for details.

BFM signal parameters

Name	Туре	Description
clk	std_logic	The clock signal used to read and write
		data in/out of the AXI4 BFM.
axi_if	t_axi_if	See table "Signal record 'axi_if"

Note: All signals are active high. See AXI4 documentation for protocol description.

For more information on the AXI4 signals, please see the AXI4 specification.

Signal record 'axi_if'

	Record element	Туре
	write_address_channel	t_axi_write_address_channel
	write_data_channel	t_axi_write_data_channel
	write_response_channel	t_axi_write_response_channel
	read_address_channel	t_axi_read_address_channel
	read_data_channel	t_axi_read_data_channel

BFM details

BFM procedure details and examples

Procedure axi write()

Description

axi write(awid value, awaddr value, awlen value, awsize value, awburst value, awlock value, awcache value, awprot value, awgos value, awregion value, awuser_value, wdata_value, wstrb_value, wuser_value, buser_value, bresp_value, msg, clk, axi_if, [scope, [msg_id_panel, [config]]])

The axi write() procedure writes the given data to the given address of the DUT, using the AXI4 protocol. For protocol details, see the AXI4 specification.

A log message is written if ID BFM is enabled for the specified message ID panel.

The procedure reports an alert if:

- wready does not occur within max wait cycles clock cycles (alert level: max wait cycles severity, set in the config)
- awready does not occur within max wait cycles clock cycles (alert level: max wait cycles severity, set in the config)
- bvalid is not set within max_wait_cycles clock cycles (alert level: max_wait_cycles_severity, set in the config)

Examples:

```
axi write(
   awid value
                 => x''01'',
  awaddr value \Rightarrow x"00000004",
  awlen value => x"01",
  awsize value => 4,
  awburst value => INCR,
  awlock value => NORMAL,
   awcache value => "0000",
   awprot value => UNPRIVILEGED UNSECURE DATA,
   awqos value => "0000",
   awregion value => "0000",
   awuser value => x"01",
   wdata value => t slv array'(x"12345678", x"33333333"),
   wstrb value => t slv array'(x"F", x"F"),
   wuser value
               => t slv array'(x"01", x"01"),
  buser value => v buser value,
   bresp value
                => v bresp value,
                 => "Writing data to Peripheral 1",
   msq
   clk
                 => clk,
                 => axi if,
   axi if
   scope
                 => C SCOPE,
   msg id panel => shared msg id panel,
                 => C AXI BFM CONFIG DEFAULT);
   config
 axi write(
  awaddr value
                 => x"00000004",
  wdata value
                 => t slv array'(x"12345678", x"33333333"),
  buser value
                 => v buser value,
                 => v bresp value,
  bresp value
                 => "Writing data to Peripheral 1");
   msq
```

Suggested usage (requires local overload, see section 5):

```
axi_write(C_ADDR_DMA, x"AAAA", "Writing data to DMA");
axi_write(C_ADDR_MEMORY, x"FF", v_data_array, "Writing 256 data words to MEMORY");
```

axi_read()

axi_read(arid_value, araddr_value, arlen_value, arsize_value, arburst_value, arlock_value, arcache_value, arprot_value, arqos_value, arregion_value, aruser_value, radta_value, rresp_value, ruser_value, msq, clk, axi_if, [scope, [msg_id_panel, [config, [proc_name]]]])

The axi_read() procedure reads data from the DUT at the given address, using the AXI4 protocol. For protocol details, see the AXI4 specification. The read data is placed on the output 'rdata value' when the read has completed.

- The argument "ext_proc_call" is intended to be used internally, when the procedure is called by axi_check().
- A log message is written if ID_BFM is enabled for the specified message ID panel. This will only occur if the argument proc_name is left unchanged.

The procedure reports an alert if:

- The received rid is different from the transmitted arid_value
- arready does not occur within max_wait_cycles clock cycles (alert level: max_wait_cycles_severity, set in the config)
- rvalid is not set within max_wait_cycles clock cycles (alert level: max_wait_cycles_severity, set in the config)

Examples:

```
axi read(
  arid value
                => x"01",
 araddr value => x"00000004"
 arlen value \Rightarrow x"01",
 arsize value => 4,
 arburst value => INCR.
 arlock value => NORMAL,
  arcache value => "0000",
  arprot value => UNPRIVILEGED UNSECURE DATA,
  argos value => "0000",
  arregion value => "0000",
  aruser value => x"01",
  rdata value => v rdata value,
              => v rresp value,
 rresp value
  ruser value => v ruser value,
                => "Read from Peripheral 1",
  msq
  clk
                => clk.
 axi if
                => axi if,
                => C SCOPE,
  msg id panel => shared msg id panel,
  config
                => C AXI BFM CONFIG DEFAULT);
axi read(
  araddr value => x"00000004",
 rdata value => v rdata value,
 rresp value => v rresp value,
  ruser value => v ruser value,
                => "Read from Peripheral 1",
 msg
                => clk,
  clk
                => axi if);
  axi if
```

Suggested usage (requires local overload, see section 5):

```
axi_read(C_ADDR_IO, v_data_out, "Reading from IO device");
axi_read(C_ADDR_MEMORY, x"FF", v_data_array_out, "Reading 256 data words from MEMORY");
```

axi_check()

axi_check(arid_value, araddr_value, arlen_value, arsize_value, arburst_value, arlock_value, arcache_value, arprot_value, arqos_value, arregion_value, aruser_value, rdata_exp, rresp_exp, ruser_exp, msg, clk, axi_if, [alert_level, [scope, [msg_id_panel, [config]]]])

The axi_check() procedure reads data from the DUT at the given address, using the AXI4 protocol. For protocol details, see the AXI4 specification. After reading data from the AXI4 bus, the read data is compared with the expected data, 'rdata_exp'.

- If the check was successful, and the read data matches the expected data, a log message is written with ID_BFM (if this ID has been enabled).
- If the read data did not match the expected data, an alert with severity 'alert_level' will be reported.

The procedure also report alerts for the same conditions as the axi_read() procedure.

Examples:

```
axi check(
  arid value
                => x"01",
 araddr value => x''00000004'',
 arlen value => x''01'',
 arsize value => 4,
  arburst value => INCR,
  arlock value => NORMAL,
  arcache value => "0000",
  arprot value => UNPRIVILEGED UNSECURE DATA,
  argos value => "0000",
  arregion value => "0000",
  aruser value => x"01",
  rdata exp
                => t slv array'(x"12345678", x"33333333"),
  rresp exp
                => t xresp array' (OKAY, OKAY),
               => t slv array'(x"00", x"00"),
  ruser_exp
                => "Check data from Peripheral 1",
  msq
                => clk,
  clk
  axi if
                => axi if,
  alert level => ERROR,
  scope
                => C SCOPE,
  msg id panel => shared msg id panel,
                => C AXI BFM CONFIG DEFAULT);
  config
axi check(
  \overline{\text{araddr value}} => x''00000004'',
  rdata exp
                => v rdata exp,
                => "Check data from Peripheral 1",
 msq
  clk
                 => clk.
  axi if
                 => axi if);
```

Suggested usage (requires local overload, see section 5):

```
axi_check(C_ADDR_UART_RX, x"3B", "Checking data in UART RX register");
axi_check(C_ADDR_MEMORY, x"FF", v_rdata_exp_array, "Checking 256 data words from MEMORY");
```

init_axi_if_signals()

init_axi_if_signals(addr_width, data_width, id_width, user_width)

This function initializes the AXI4 interface. All the BFM outputs are set to zeros ('0') and BFM inputs are set to 'Z'.

Note: This function assumes that awid, bid, arid and rid shares a common width (id_width) and that awuser, buser, aruser, ruser also share a common width (user_width)

Example

```
axi if <= init axi if signals(addr width, data width, id width, user width);</pre>
```

BFM Configuration record

Type name: t_axi_bfm_config			
Record element	Туре	C_AXI_BFM_CONFIG_DEFAULT	Description
max_wait_cycles	natural	10	Used for setting the maximum cycles to wait before an alert is issued when waiting
	Haturai		for ready and valid signals from the DUT.
max_wait_cycles_severity	t_alert_level	TB_FAILURE	The above timeout will have this severity
clock_period	time	-1 ns	Period of the clock signal.
clock_period_margin	time	0 ns	Input clock period margin to specified clock_period
clock_margin_severity	t_alert_level	TB_ERROR	The above margin will have the severity
setup_time	time	-1 ns	Setup time for generated signals. Suggested value is clock_period/4.
			An alert is reported if setup_time exceed clock_period/2.
hold_time	time	-1 ns	Hold time for generated signals. Suggested value is clock_period/4.
			An alert is reported if hold_time exceed clock_period/2.
bfm_sync	t_bfm_sync	SYNC_ON_CLOCK_ONLY	When set to SYNC_ON_CLOCK_ONLY the BFM will enter on the first falling edge,
			estimate the clock period, synchronise the output signals and exit ¼ clock period
			after a succeeding rising edge.
			When set to SYNC_WITH_SETUP_AND_HOLD the BFM will use the configured
			setup_time, hold_time and clock_period to synchronise output signals with clock
			edges.
match_strictness	t_match_strictness		Matching strictness for std_logic values in check procedures.
		MATCH_EXACT	MATCH_EXACT requires both values to be the same. Note that the expected value
			can contain the don't care operator '-'.
			MATCH_STD allows comparisons between 'H' and '1', 'L' and '0' and '-' in both
			values.
num_aw_pipe_stages	natural	1	Write Address Channel pipeline steps
num_w_pipe_stages	natural	1	Write Data Channel pipeline steps
num_ar_pipe_stages	natural	1	Read Address Channel pipeline steps
num_r_pipe_stages	natural	1	Read Data Channel pipeline steps
num_b_pipe_stages	natural	1	Response Channel pipeline steps
id_for_bfm	t_msg_id	ID_BFM	The message ID used as a general message ID in the AXI BFM
id_for_bfm_wait	t_msg_id	ID_BFM_WAIT	The message ID used for logging waits in the AXI BFM
id_for_bfm_poll	t_msg_id	ID_BFM_POLL	The message ID used for logging polling in the AXI BFM

3 Additional Documentation

For additional documentation on the AXI4 standard, please see the AXI4 specification "AMBA® AXI™ and ACE™ Protocol Specification", available from ARM.

4 Compilation

The AXI4 BFM may only be compiled with VHDL 2008. It is dependent on the UVVM Utility Library (UVVM-Util), which is only compatible with VHDL 2008. See the separate UVVM-Util documentation for more info. After UVVM-Util has been compiled, the axi_bfm_pkg.vhd BFM can be compiled into any desired library. See the UVVM Essential Mechanisms located in uvvm_vvc_framework/doc for information about compile scripts.

4.1 Simulator compatibility and setup

See README.md for a list of supported simulators. For required simulator setup see UVVM-Util Quick reference.

5 Local BFM overloads

A good approach for better readability and maintainability is to make simple, local overloads for the BFM procedures in the TB process. This allows calling the BFM procedures with the key parameters only e.g.

```
axi write (C ADDR PERIPHERAL 1, C TEST DATA, "Sending data to Peripheral 1");
rather than
  axi write(
    awid value
                   => x''01'',
    awad\overline{d}r value => x"00000004",
    awlen value
                   => x"01",
    awsize value
                   => 4,
    awburst value => INCR,
    awlock value
                   => NORMAL,
    awcache value => "0000",
    awprot value
                   => UNPRIVILEGED UNSECURE DATA,
    awgos value
                   => "0000",
    awregion value => "0000",
    awuser value \Rightarrow x"01",
    wdata value
                  \Rightarrow t slv array'(x"12345678", x"33333333"),
    wstrb_value
                 => t slv array'(x"F", x"F"),
                 => t slv array'(x"01", x"01"),
    wuser value
    buser_value
                   => v buser value,
    bresp value
                   => v bresp value,
                   => "Writing data to Peripheral 1",
    msq
                   => clk.
    clk
                   => axi if,
    axi if
    scope
                   => C SCOPE,
                   => shared msg id panel,
    msq id panel
                   => C AXI BFM CONFIG DEFAULT);
    confia
By defining the local overload as e.g.:
    procedure axi write(
      constant addr value
                            : in unsigned;
      constant data value
                            : in std logic vector;
                             : in string
      constant msg
      variable v buser value : std logic vector(C USER WIDTH-1 downto 0);
      variable v bresp value : t xresp;
    begin
      axi write(
                       => x"00",
                                                        -- Setting a default value
        awid value
        awaddr value => addr value,
                                                        -- keep as is
        awlen value
                       => x''00'''
                                                        -- Set to length=1
                                                        -- Setting a default value
        awsize value
                       => 4,
                                                        -- Setting a default value
        awburst value => INCR,
```

```
awlock value => NORMAL,
                                                                -- Setting a default value
    awcache value => "0000",
                                                               -- Setting a default value
    awprot value => UNPRIVILEGED UNSECURE DATA, -- Setting a default value
                                           D_UNSECURE_DATA, -- Setting a default value
-- keep as is
-- Setting a default value
-- Setting a default value
-- Setting a default value
-- Assigning to a local var
-- keep as is
-- Assigning to a local var
-- keep as is
    awgos value => "0000",
    awregion value => "0000",
    awuser value \Rightarrow x"01",
                       => data value,
    wdata value
    wstrb value
                     => x"f"
    wuser value
                       => x"01",
                       => v buser value,
                                                                -- Assigning to a local variable
    buser value
                        => v bresp value,
                                                                -- Assigning to a local variable
    bresp_value
                        => msq,
    msa
    clk
                        => clk.
                                                                -- Clock signal
    axi_if => axi_if,
scope => C CCOPT
                                                                -- Signal must be visible in local process scope
                                                                -- Setting a default value
    msg id panel => shared msg id panel,
                                                                -- Use global, shared msg id panel
                                                                -- Use locally defined configuration or C AXI BFM CONFIG DEFAULT
    config
                        => C AXI BFM CONFIG LOCAL);
end;
```

Using a local overload like this also allows the following – if wanted:

- Have address value as natural and convert in the overload
- Set up defaults for constants. May be different for two overloads of the same BFM
- Apply dedicated msg_id_panel to allow dedicated verbosity control

IMPORTANT

This is a simplified Bus Functional Model (BFM) for AXI4.

The given BFM complies with the AXI4 protocol and thus allows a normal access towards an AXI4 interface. This BFM is not AXI4 protocol checker.

For a more advanced BFM please contact Bitvis AS at support@bitvis.no
